Outline

Introduction

2 Forward Process

Reverse Process

Gavish Bansal Diffusion Models August 2, 2025 2 / 79

What are Diffusion Models?

- Diffusion models are inspired by non-equilibrium thermodynamics. They define a Markov chain of diffusion steps to slowly add random noise to data and then learn to reverse the diffusion process to construct desired data samples from the noise.
- Once we are able to achieve that, we can sample a point from the conditional Gaussian distribution corresponding to a particular label and backpropagate to get to a required image from Gaussian noise.

Figure: Directed Graphical representation of Diffusion Model

August 2, 2025

3/79

Forward Diffusion Process

• Given a data point sampled from a real data distribution $x_0 \sim q(x)$, let us define a forward diffusion process in which we add a small amount of Gaussian noise to the sample in T steps, producing a sequence of noisy samples x_1, x_2, \ldots, x_T , where step sizes are controlled by a variance schedule $\{\beta_t \in (0,1)\}_{t=1}^T$.

$$q(x_t|x_{t-1}) = \mathcal{N}(x_t; \sqrt{1-\beta_t}x_{t-1}, \beta_t I), \quad q(x_{1:T}|x_0) = \prod_{t=1}^{I} q(x_t|x_{t-1})$$

• As t becomes larger, x_0 keeps on losing its properties and as $T \to \infty$, x_T converges to an isotropic Gaussian distribution.

Gavish Bansal Diffusion Models August 2, 2025 4 / 79

x_t in terms of x_0

• Using a reparameterization trick, let $\alpha_t = 1 - \beta_t$ and $\bar{\alpha}_t = \prod_{i=1}^t \alpha_i$:

$$\begin{split} \mathbf{x}_t &= \sqrt{\alpha_t} \mathbf{x}_{t-1} + \sqrt{1 - \alpha_t} \epsilon_{t-1} \quad \text{where } \epsilon_{t-1}, \epsilon_{t-2}, \dots \sim \mathcal{N}(\mathbf{0}, \mathbf{I}) \\ &= \dots \\ &= \sqrt{\bar{\alpha}_t} \mathbf{x}_0 + \sqrt{1 - \bar{\alpha}_t} \epsilon \\ q(\mathbf{x}_t \mid \mathbf{x}_0) &= \mathcal{N}(\mathbf{x}_t; \sqrt{\bar{\alpha}_t} \mathbf{x}_0, (1 - \bar{\alpha}_t) \mathbf{I}) \end{split}$$

• Usually, we can afford a larger update step when the sample gets noisier, so $\beta_1 < \beta_2 < \dots < \beta_T$ and therefore $\bar{\alpha}_1 > \dots > \bar{\alpha}_T$.

Gavish Bansal Diffusion Models August 2, 2025 5/79

Reverse Diffusion Process

- To reconstruct the original image from Gaussian noise, we try to learn the distribution $q(x_{t-1} \mid x_t)$.
- If β_t is small enough, this reverse process is approximately Gaussian.
- Although we cannot compute this distribution exactly, we can derive it conditioned on x_0 :

$$q(\mathbf{x}_{t-1} \mid \mathbf{x}_t, \mathbf{x}_0) = \mathcal{N}(\mathbf{x}_{t-1}; \tilde{\mu}(\mathbf{x}_t, \mathbf{x}_0), \tilde{\beta}_t \mathbf{I})$$

Gavish Bansal Diffusion Models August 2, 2025 6 / 79

Finding $\tilde{\mu}_t$ and $\tilde{\beta}_t$

Using Bayes' rule:

$$q(\mathbf{x}_{t-1} \mid \mathbf{x}_t, \mathbf{x}_0) = q(\mathbf{x}_t \mid \mathbf{x}_{t-1}) \frac{q(\mathbf{x}_{t-1} \mid \mathbf{x}_0)}{q(\mathbf{x}_t \mid \mathbf{x}_0)}$$

• Substituting the known Gaussians:

$$\begin{split} \tilde{\beta}_t &= \frac{1 - \bar{\alpha}_{t-1}}{1 - \bar{\alpha}_t} \beta_t \\ \tilde{\mu}_t &= \frac{1}{\sqrt{\alpha_t}} \left(x_t - \frac{1 - \alpha_t}{\sqrt{1 - \bar{\alpha}_t}} \epsilon_t \right) \end{split}$$

Gavish Bansal Diffusion Models August 2, 2025 7 / 79

Reverse Diffusion Process

• We'll now learn the backward process via a neural network:

$$p_{\theta}(x_{t-1} \mid x_t) = \mathcal{N}(x_{t-1}; \mu_{\theta}(x_t, t), \Sigma_{\theta}(x_t, t))$$

Objective:

$$\min_{\theta} - \mathbb{E}_{x_0 \sim q}[\log p_{\theta}(x_0)]$$

Using KL divergence:

$$\mathcal{L}_{\mathsf{VLB}} = \mathbb{E}_{q(\mathbf{x}_{0:T})} \left[\log \frac{q(\mathbf{x}_{1:T}|\mathbf{x}_0)}{p_{ heta}(\mathbf{x}_{0:T})} \right] \ge -\mathbb{E}_{q(\mathbf{x}_0)} \log p_{ heta}(\mathbf{x}_0)$$
 (1)

8 / 79

Gavish Bansal Diffusion Models August 2, 2025

Further Manipulation

After some algebra, the VLB loss decomposes as:

$$\mathcal{L}_{VLB} = L_T + L_{T-1} + \dots + L_0 \tag{2}$$

where
$$L_T = D_{\mathsf{KL}}(q(\mathbf{x}_T|\mathbf{x}_0) \parallel p_{\theta}(\mathbf{x}_T))$$
 (3)

$$L_t = D_{\mathsf{KL}}(q(\mathbf{x}_t|\mathbf{x}_{t+1},\mathbf{x}_0) \parallel p_{\theta}(\mathbf{x}_t|\mathbf{x}_{t+1})) \quad \text{for } 1 \le t \le T-1$$
(4)

$$L_0 = -\log p_{\theta}(\mathbf{x}_0|\mathbf{x}_1) \tag{5}$$

REMAINING DIFFUSION SLIDES HERE

Speech Restoration

- Diffusion model discussed above will be able to generate images/speech but cann't be used directly for speech restoration.
- bto deal with speech restoration using diffusion model we need to study something called SDE(Stochastic differential equation.
- The basic idea will be to generate noisy version to speech from clean speech by adding some noise in a directed manner and if we are able to simulate the backward direction of this process somehow(as done in diffusion model) then we will be able to generate clean speech from noisy speech following that reverse process.

What are Stochastic Differential Equations (SDEs)?

- SDEs are differential equations where one or more terms are stochastic processes, meaning they incorporate random noise.
- They are used to model systems that evolve randomly over time.
- Unlike ordinary differential equations (ODEs) which describe deterministic change, SDEs account for inherent uncertainty.

example_random_walk.png

Gavish Bansal Diffusion Models August 2, 2025 12 / 79

Review: Ordinary Differential Equations (ODEs)

- An ODE describes the rate of change of a variable with respect to another, typically time.
- General form: $\frac{X_t}{t} = f(X_t, t)$
- Solution X_t is a deterministic path given initial conditions.

Example: Simple Growth Model

$$\frac{X_t}{t} = rX_t \implies X_t = X_0e^{rt}$$

- Here, r is the constant growth rate.
- The future value X_t is perfectly predictable.

13 / 79

Review: Stochastic Differential Equations (SDEs)

- An SDE models the rate of change of a system with both deterministic and random components.
- General form (Itô): $X_t = \mu(X_t, t)t + \sigma(X_t, t)W_t$
- Solution X_t is a stochastic process outcomes are random, even with the same initial conditions.

Example: Geometric Brownian Motion (GBM)

$$X_t = rX_t t + \sigma X_t W_t \quad \Rightarrow \quad X_t = X_0 \exp\left(\left(r - \frac{1}{2}\sigma^2\right)t + \sigma W_t\right)$$

- r: drift (expected growth rate), σ : volatility.
- Future value X_t is uncertain due to Brownian motion W_t .

4 D F 4 B F 4 E F 4 E F 9) Q (*)

Algebraic Equation \rightarrow ODE \rightarrow SDE

Algebraic Equation (Deterministic Motion):

$$X_t = X_0 + vt$$

Object moves at constant velocity v.

Ordinary Differential Equation (ODE):

$$\frac{X_t}{t} = v$$

Expresses rate of change explicitly.

Stochastic Differential Equation (SDE):

- Suppose the velocity has random fluctuations (e.g., due to noise or uncertainty).
- A naive model: $\frac{X_t}{t} = v + \eta_t$, where η_t is white noise.
- But this is ill-defined in classical calculus.
- Using Itô calculus, we write:

Key Concept: The Wiener Process (Brownian Motion)

- Also known as Brownian motion, denoted W_t .
- It's the primary source of randomness in SDEs.
- Properties:
 - $W_0 = 0$ (starts at zero).
 - ② Independent increments: For $0 \le s < t < u < v$, $W_t W_s$ and $W_v W_u$ are independent.
 - **3** Stationary increments: $W_t W_s \sim \mathcal{N}(0, t s)$.
 - Ontinuous paths (almost surely).
 - Nowhere differentiable (a key distinction from ODEs).

16 / 79

Gavish Bansal Diffusion Models August 2, 2025

General Form of an Itô SDE

- Most commonly, SDEs are defined in the sense of Itô calculus due to the non-differentiability of the Wiener process.
- An Itô SDE for a process X_t is written as:

$$X_t = f(X_t, t) t + g(X_t, t) W_t$$

- Where:
 - X_t : Random Process (evolve overtime)
 - $f(X_t, t)$: **Drift coefficient** (deterministic part).
 - $g(X_t, t)$: **Diffusion coefficient** (stochastic part).
 - W_t : Infinitesimal increment of a Wiener process.

Gavish Bansal Diffusion Models August 2, 2025 17 / 79

Ornstein-Uhlenbeck Process

A classic example of a mean-reverting stochastic process.

SDE Form:

$$X_t = \kappa(\theta - X_t)t + \sigma W_t$$

- $\kappa > 0$: rate of mean reversion.
- θ : **long-term mean** (the level to which the process tends to return).
- σ : **volatility** of the process.
- W_t : standard Brownian motion.

Properties:

• Has an explicit solution:

$$X_t = \theta + (X_0 - \theta)e^{-\kappa t} + \sigma \int_0^t e^{-\kappa(t-s)} W_s$$

• As $t \to \infty$, $X_t \to \theta$ in distribution.

18 / 79

Mean-Reverting Process

Definition

A stochastic process is said to be **mean-reverting** if it tends to drift toward a long-term average (mean) value over time, even after random fluctuations.

Example: Ornstein-Uhlenbeck Process

$$X_t = \kappa(\theta - X_t)t + \sigma W_t$$

Key Insight: If $X_t > \theta$, drift becomes negative, pulling it down. If $X_t < \theta$, drift becomes positive, pulling it up.

Used In: Modeling interest rates, volatility, neuron potentials, physical forces, etc.

- 4 ロ ト 4 個 ト 4 差 ト 4 差 ト - 差 - かくで

Variance Exploding vs Variance Preserving SDEs

1. Variance Preserving SDE (VP-SDE)

$$X_t = -\frac{1}{2}\beta(t)X_tt + \sqrt{\beta(t)}W_t$$

- ullet Mean is preserved over time: $\mathbb{E}[X_t] pprox X_0$
- Variance increases gradually: noise dominates as $t \to T$
- Used in Denoising Diffusion Probabilistic Models (DDPM)

2. Variance Exploding SDE (VE-SDE)

$$X_t = \sigma(t)W_t$$
, with $\sigma(t)$ increasing

- No drift: $\mathbb{E}[X_t] = X_0$
- Variance explodes rapidly: $Var(X_t) = \int_0^t \sigma^2(s) s$

Gavish Bansal Diffusion Models August 2, 2025 20 / 79

Itô's Lemma

- Analogous to the chain rule in standard calculus.
- Let X_t satisfy: $X_t = \mu(X_t, t)t + \sigma(X_t, t)W_t$
- For a twice-differentiable function $f(X_t, t)$:

$$f(X_t, t) = \left(\frac{\partial f}{\partial t} + \mu \frac{\partial f}{\partial X} + \frac{1}{2}\sigma^2 \frac{\partial^2 f}{\partial X^2}\right) t + \sigma \frac{\partial f}{\partial X} W_t$$

• The Itô correction term $\frac{1}{2}\sigma^2\frac{\partial^2 f}{\partial X^2}$ arises from the quadratic variation of Brownian motion.

Gavish Bansal Diffusion Models August 2, 2025 21 / 79

Example: Itô's Lemma for $f(X_t) = X_t^2$

Let:

$$X_t = \mu t + \sigma W_t$$

where μ, σ are constants and W_t is standard Brownian motion.

Define: $f(X_t) = X_t^2$

Apply Itô's Lemma:

$$f(X_t) = \left(\frac{\partial f}{\partial X}\mu + \frac{1}{2}\frac{\partial^2 f}{\partial X^2}\sigma^2\right)t + \frac{\partial f}{\partial X}\sigma W_t$$

Compute derivatives:

$$\frac{\partial f}{\partial X} = 2X_t, \quad \frac{\partial^2 f}{\partial X^2} = 2$$

Result:

$$(X_t^2) = (2X_t\mu + \sigma^2)t + 2X_t\sigma W_t$$

Insight: The σ^2 term appears only due to stochasticity — it is the **Itô** correction.

SDE for Speech Reconstruction

SDE:

$$dx_t = \gamma(y - x_t) dt + g(t) dw$$
 (6)

$$g(t) = \sigma_{\min} \left(\frac{\sigma_{\max}}{\sigma_{\min}} \right)^t \sqrt{2 \log \left(\frac{\sigma_{\max}}{\sigma_{\min}} \right)}$$
 (7)

- Observe this forward process takes clean speech to noisy one as $T \to \infty$.
- Noise Schedule is exponentially increasing for a fix value to another. (So, it is variance exploding Itô SDE)
- Also this Itô SDE is mean reverting.
- Important point is that for this SDE Pretubation kernel and reverse SDE can be found explicitly.

Gavish Bansal Diffusion Models August 2, 2025 23 / 79

Pertubation Kernel

$$p_{0t}(x_t \mid x_0, y) = \mathcal{N}_{\mathbb{C}}\left(x_t; \mu_{x_0, y}(t), \sigma(t)^2 \mathbf{I}\right)$$

where,

$$\mu_{x_0,y}(t) = e^{-\gamma t} x_0 + (1 - e^{-\gamma t}) y$$

$$\sigma(t)^2 = \frac{\sigma_{\min}^2\left(\left(\frac{\sigma_{\max}}{\sigma_{\min}}\right)^{2t} - e^{-2\gamma t}\right)\log\left(\frac{\sigma_{\max}}{\sigma_{\min}}\right)}{\gamma + \log\left(\frac{\sigma_{\max}}{\sigma_{\min}}\right)}$$

Gavish Bansal Diffusion Models August 2, 2025 24 / 79

Pertubation Kernel Derivation(intutive)

- First observe that noise added has zero mean at each step.
- For mean consider ODE which comes after substituting g(t) = 0.
- After this use initial condition of x_0 to get:

$$\mu_{x_0,y}(t) = e^{-\gamma t} x_0 + (1 - e^{-\gamma t}) y$$

• Here it could be easily seen that as $T \to \infty$, $\mu_{x_0,y}(t) \to y$. So, it is indeed mean reverting.

Gavish Bansal Diffusion Models August 2, 2025 25 / 79

Pertubation Kernel Derivation(formal)

OU SDE:

$$(x_t) = \gamma(y - x_t)t + g(t)d(w_t)$$

$$(e^{\gamma t}x_t) = \gamma y e^{\gamma t}t + g(t)e^{\gamma t}d(w_t)$$

$$e^{\gamma t}x_t = x_0 + \gamma y \int_0^t e^{\gamma s}s + \int_0^t g(s)e^{\gamma s}d(w_s)$$

$$x_t = x_0 e^{-\gamma t} + y(1 - e^{-\gamma t}) + \int_0^t g(s)e^{-\gamma(t-s)}d(w_s)$$

• This is of form:

$$x_t = \mu(x_0, y, t) + \epsilon_t$$

- $\mu(x_0, y, t) = x_0 e^{-\gamma t} + y(1 e^{-\gamma t})$
- $\epsilon_t = \int_0^t g(s)e^{-\gamma(t-s)}d(w_s)$ which is a guassian with 0 mean and finite covariance.

- 4 ロ ト 4 個 ト 4 差 ト 4 差 ト - 差 - 夕 Q (C)

26 / 79

Pertubation Kernel Derivation(formal)

Mean:

$$\mathbb{E}[x_t] = x_0 e^{-\gamma t} + y(1 - e^{-\gamma t})$$

Covariance Matrix:

$$\epsilon_t = \int_0^t g(s)e^{-\gamma(t-s)}d(w_s)$$

$$Var[x_t] = \mathbb{E}[x_t^2] - \mathbb{E}[x_t]^2$$

$$Var[x_t] = \mathbb{E}[\epsilon_t^2]$$

$$Var[x_t] = \int_0^t g(s)^2e^{-2\gamma(t-s)}d(s)$$

Gavish Bansal Diffusion Models August 2, 2025 27 / 79

Perturbation Kernel Derivation (Formal)

- To derive the closed-form expression for the perturbation kernel variance, we substitute the noise scale g(t) into the stochastic process.
- The resulting variance of the perturbation kernel is:

$$\sigma(t)^2 = \frac{\sigma_{\min}^2 \left(\left(\frac{\sigma_{\max}}{\sigma_{\min}} \right)^{2t} - e^{-2\gamma t} \right) \log \left(\frac{\sigma_{\max}}{\sigma_{\min}} \right)}{\gamma + \log \left(\frac{\sigma_{\max}}{\sigma_{\min}} \right)}$$

ullet This expression captures both exponential decay (via γ) and geometric growth (via the log-variance schedule), allowing smooth control over the noise level in diffusion-based models.

Gavish Bansal Diffusion Models August 2, 2025 28 / 79

Reverse SDE

Given forward process as:

$$dx_t = f(x_t, t) dt + g(t) dw,$$
 (8)

Coresponding reverse process is given by:

$$dx_t = \left[f(x_t, t) - g(t)^2 \nabla_{x_t} \log p_t(x_t) \right] dt + g(t) d\bar{w}, \tag{9}$$

• Interpretation:

$$x_{t+1} = x_t + f(x_t, t) dt + g(t) dw$$

then,

$$x_t = x_{t+1} - [f(x_{t+1}, t+1) - g(t+1)^2 \nabla_{x_{t+1}} \log p_{t+1}(x_{t+1})] dt + g(t+1) dt$$

29 / 79

Fokker-Planck Equation

- The Fokker-Planck equation governs the time evolution of the probability density function p(x, t) of a stochastic process.
- For an Itô SDE of the form:

$$\mathrm{d}x_t = f(x_t, t)\,\mathrm{d}t + g(x_t, t)\,\mathrm{d}w_t$$

the corresponding Fokker-Planck equation is:

$$\frac{\partial p(x,t)}{\partial t} = -\nabla_x \cdot (f(x,t)p(x,t)) + \frac{1}{2}\nabla_x^2 : (D(x,t)p(x,t))$$

• Here, the diffusion matrix is:

$$D(x,t) = g(x,t)g(x,t)^{\top}$$

Gavish Bansal Diffusion Models August 2, 2025 30 / 79

Fokker-Planck Equation

- The Fokker-Planck equation tells us how probability "flows" in time.
- **Drift term**: $-\nabla_x \cdot (f(x,t)p(x,t))$ moves the density along vector field f.
- **Diffusion term**: $\frac{1}{2}\nabla_x^2$: (D(x,t)p(x,t)) spreads the density (adds uncertainty).
- In score-based diffusion models, the reverse-time SDE is derived from the Fokker-Planck equation by incorporating the score function:

$$\nabla_x \log p_t(x)$$

• This forms the basis of reverse diffusion and generative sampling in SDE-based speech and image restoration models.

4□ > 4□ > 4 = > 4 = > = 90

31 / 79

Gavish Bansal Diffusion Models August 2, 2025

Reverse Process Derivation

- Some Basic Notation:
 - $P_t(x)$: Probability density function of x(t).
 - f(x,t) and g(t): Drift and Diffusion term respectively.
 - T: Total number of steps considered.
 - ullet \sim : Represent corresponding terms for reverse process.
- Some important points:
 - $\tilde{x}(t) = x(T-t)$
 - $\tilde{P}_t(x) = P_{T-t}(x)$
 - $\tilde{g}(t) = g(T t)$ (just revert the diffusion term)

32 / 79

Gavish Bansal Diffusion Models August 2, 2025

Reverse Process Derivation

Fokker plank equation for reverse Process:

$$\frac{\partial \tilde{p}_t(x)}{\partial t} = -\nabla_{\tilde{x_t}} \cdot (\tilde{f}(x,t)\tilde{p}_t(x)) + \frac{1}{2}\tilde{g}(t)\nabla_{\tilde{x_t}^2\tilde{p}_t(x)}$$

Substitute s = T - t

$$\frac{\partial p_s(x)}{\partial t} = -\nabla_{x_s} \cdot (\tilde{f}_t(x)p_s(x)) + \frac{1}{2}g(s)^2 \nabla_{x_s}^2 p_s(x)$$

Fokker plank equation for forward process for s = T-t:

$$\frac{\partial p_s(x)}{\partial t} = -\frac{\partial p_s(x)}{\partial s} = \nabla_{x_s} \cdot (f_s(x)p_s(x)) - \frac{1}{2}g(s)^2 \nabla_{x_s}^2 p_s(x)$$

Gavish Bansal Diffusion Models August 2, 2025 33 / 79

Reverse Process Derivation

• Combine above 2 equations:

$$\nabla_{\mathsf{x}_{\mathsf{s}}} \cdot \left(\tilde{f}_{\mathsf{t}}(\mathsf{x}) p_{\mathsf{s}}(\mathsf{x}) \right) = - \nabla_{\mathsf{x}_{\mathsf{s}}} \cdot \left(f_{\mathsf{s}}(\mathsf{x}) p_{\mathsf{s}}(\mathsf{x}) \right) + g(\mathsf{s})^2 \nabla_{\mathsf{x}_{\mathsf{s}}}^2 p_{\mathsf{s}}(\mathsf{x})$$

Solving this:

$$\tilde{f}_t(x) = -f_{T-t}(x) + g(T-t)^2 \nabla_{x_t} P_{T-t}(x)$$

•

(ロト 4년) + 4분 + 4분 + 1분 - 1900은

Speech Enhancement Algorithm

- Observe given the noisy speech only unknown factor in reverse process is $\nabla_{\mathbf{x}_t} \log p_t(\mathbf{x}_t)$ which is known as score function
- If somehow we are able to learn this, then we'll be able to generate clean speech.
- Directly computing the score function $\nabla_{\mathbf{x}_t} \log p_t(\mathbf{x}_t)$ is intractable for complex data.
- Therefore, we train a neural network $s_{\theta}(\mathbf{x}_t, t)$ to approximate this score function.
- In the case of conditional Gaussian distribution $p_t(\mathbf{x}_t|\mathbf{x}_0)$, the score function is known:

$$abla_{\mathsf{x}_t} \log p_t(\mathsf{x}_t|\mathsf{x}_0) = -rac{\mathsf{x}_t - oldsymbol{\mu}(t|\mathsf{x}_0)}{\sigma^2(t)}$$

Gavish Bansal Diffusion Models August 2, 2025 35 / 79

Score Function Estimation

Suppose the noisy observation is:

$$\mathbf{x}_t = \boldsymbol{\mu}(t|\mathbf{x}_0) + \sigma(t) \cdot \mathbf{z}, \quad \mathbf{z} \sim \mathcal{N}(0, \mathbf{I})$$

• Then the score simplifies to:

$$abla_{\mathsf{x}_t} \log
ho_t(\mathsf{x}_t|\mathsf{x}_0) = -rac{\mathsf{z}}{\sigma(t)}$$

- The neural network $s_{\theta}(\mathbf{x}_t, t)$ is trained to match this true score.
- The training objective becomes:

$$\mathbb{E}_{\mathsf{x}_0,\mathsf{z},t} \left[\left\| s_{\theta}(\mathsf{x}_t,t) + \frac{\mathsf{z}}{\sigma(t)} \right\|^2 \right]$$

 This is known as denoising score matching, and is a core technique in DDPMs and score-based generative models.

Significance of score function

 Langevin dynamics is a sampling method that uses the score function to generate samples from a distribution:

$$\mathbf{x}_{k+1} = \mathbf{x}_k + \frac{\eta}{2} \nabla_{\mathbf{x}} \log p(\mathbf{x}_k) + \sqrt{\eta} \cdot \boldsymbol{\epsilon}, \quad \boldsymbol{\epsilon} \sim \mathcal{N}(\mathbf{0}, \mathbf{I})$$

- This simulates a diffusion process where particles move towards high-density regions of $p(\mathbf{x})$.
- So, score of any distribution gives us full information about corresponding distribution which is a little bit intutive as knowledge of gradient at each point and normalization constraint ensures this.
- This forms the basis for score-based generative models and denoising diffusion probabilistic models (DDPMs).

Forward and Reverse Processes

Forward SDE (Ornstein-Uhlenbeck process):

$$d\mathbf{x}_{\tau} = \gamma(\mathbf{y} - \mathbf{x}_{\tau})d\tau + g(\tau)d\mathbf{w}$$

Perturbation kernel solution:

$$p_{0,\tau}(\mathbf{x}_{\tau}|\mathbf{x}_{0},\mathbf{y}) = \mathcal{N}_{\mathbb{C}}(\mathbf{x}_{\tau};\boldsymbol{\mu},\sigma(\tau)^{2}\mathbf{I})$$

Closed-form mean and variance:

$$\begin{split} \boldsymbol{\mu} &= e^{-\gamma \tau} \mathbf{x}_0 + (1 - e^{-\gamma \tau}) \mathbf{y} \\ \sigma(\tau)^2 &= \frac{\sigma_{\min}^2((\sigma_{\max}/\sigma_{\min})^{2\tau} - e^{-2\gamma \tau}) \log(\sigma_{\max}/\sigma_{\min})}{\gamma + \log(\sigma_{\max}/\sigma_{\min})} \end{split}$$

Gavish Bansal Diffusion Models August 2, 2025 39 / 79

Score Function Estimation

Score function of perturbation kernel:

$$abla_{\mathbf{x}_{ au}}\log p_{0, au}(\mathbf{x}_{ au}|\mathbf{x}_{0},\mathbf{y}) = -rac{\mathbf{x}_{ au}-oldsymbol{\mu}}{\sigma(au)^{2}}$$

Denoising score matching objective:

$$\mathcal{J}^{(\mathsf{DSM})}(\phi) = \mathbb{E}\left[\left\|\mathbf{s}_{\phi}(\mathbf{x}_{ au},\mathbf{y}, au) + rac{\mathbf{z}}{\sigma(au)}
ight\|_2^2
ight]$$

- Training process:
 - Sample $au \sim \mathcal{U}[au_{\epsilon}, T]$
 - Generate $\mathbf{x}_{ au} = \boldsymbol{\mu} + \sigma(au)\mathbf{z}$
 - Train DNN \mathbf{s}_{ϕ} to estimate score

40 / 79

Limitations of Existing Approaches

• Predictive Models:

- Dominate speech restoration, learning a deterministic mapping.
- Can distort target speech and suffer from generalizability issues.
- Tend to "smooth out" fine-grained details (regression to the mean).

Generative Models (Diffusion Models):

- Show great ability in bridging performance gaps and can outperform predictive models for certain corruption types.
- High Computational Burden: Require running a neural network for each reverse diffusion step.
- Can produce vocalizing and breathing artifacts in adverse conditions.

41 / 79

Predictive Artifacts in Speech Spectrograms

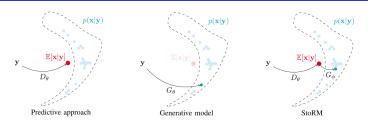

- Inverse problems (denoising, dereverberation, bandwidth extension).
- Predictive models trained with L^2 regression result in:
 - Smoothing
 - Loss of fine-grained details
 - Over-denoising
- Similar to edge loss in image denoising.

42 / 79

StoRM: Bridging the Gap

- Proposed: Stochastic Regeneration Approach (StoRM).
- Combines predictive and generative models.
- Uses an estimate from a predictive model as a guide for further diffusion.
- Advantages:
 - Removes vocalizing and breathing artifacts.
 - Produces very high-quality samples.
 - Enables lighter sampling schemes with fewer diffusion steps, reducing computational burden by an order of magnitude.

Predictive vs. Generative Models: A Distributional View

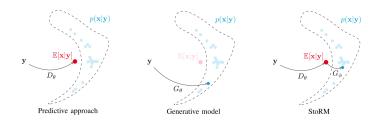

Left (Predictive approach):

- The model D_{θ} predicts a single point: $\mathbb{E}[x|y]$.
- Optimized via MSE loss; result often lies outside the high-density region of p(x|y).
- Leads to overly smooth, less natural outputs.

• Middle (Generative model):

- Attempts to sample from p(x|y) using a generative model G_{θ} .
- ullet No predictive anchor o learning is harder, especially when SNR is low.
- May require long sampling or produce unrealistic outputs if not properly regularized.

StoRM: Guided Generation for Better Modeling of p(x|y)

• Right (StoRM):

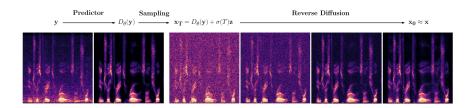

- Begins from $\mathbb{E}[x|y] = D_{\theta}(y)$ a high-SNR estimate from the predictive model.
- ullet Then refines this estimate using a score-based generative model $G_\phi.$
- Final output lies in the high-density region of p(x|y), capturing realistic variations.

Advantage:

- Easier learning than pure generative methods.
- Better perceptual quality than pure predictive methods.

4□ F 4 B F 4 E F € 9) Q(6

StoRM Inference Process Visualization

Left to Right:

- Input spectrogram y
- Predictive estimate $D_{\theta}(y)$
- Sampled noisy signal $x_T = D_{\theta}(y) + \sigma(T)z$
- Intermediate reverse diffusion steps
- Final output $x_0 \approx x$
- Demonstrates the full StoRM inference pipeline from noisy input to high-fidelity output.

Gavish Bansal Diffusion Models August 2, 2025 46 / 79

Inference Pipeline in StoRM

- The StoRM inference process reconstructs clean speech x from a corrupted observation y using a two-stage approach:
 - **1 Prediction Stage:** A predictive model $D_{\theta}(y)$ estimates an initial denoised speech signal.
 - **Sampling Stage:** Noise is added to the estimate: $x_T = D_{\theta}(y) + \sigma(T)z$, where $z \sim \mathcal{N}(0, I)$.
 - **3 Reverse Diffusion Stage:** A score-based generative model refines x_T via reverse-time SDE sampling to produce $x_0 \approx x$.
- This design provides:
 - High initial SNR to facilitate diffusion.
 - Reduction in artifacts like over-smoothing and vocoding effects.

Gavish Bansal Diffusion Models August 2, 2025 47 / 79

Interpretation of Spectrogram Transitions

- **Leftmost Panel (***y***):** Corrupted speech spectrogram (e.g., noisy, reverberated input).
- **Second Panel** ($D_{\theta}(y)$): Initial clean speech estimate from predictive model; suffers from smoothing artifacts.
- Middle Panel (x_T) : Sampled noisy version of the prediction starting point for reverse diffusion.
- Next Panels: Intermediate results during reverse diffusion. Noise gradually removed while preserving structure.
- **Rightmost Panel** (x_0): Final output a high-quality approximation of clean speech with better resolution and less distortion.

Gavish Bansal Diffusion Models August 2, 2025 48 / 79

Diffusion Process Mathematics

Modified Forward SDE:

$$\mathrm{d}\mathbf{x}_{ au} = \gamma \left(D_{ heta}(\mathbf{y}) - \mathbf{x}_{ au} \right) \mathrm{d} au + \mathbf{g}(au) \, \mathrm{d}\mathbf{w}$$

Perturbation Kernel:

$$p_{0, au}(\mathbf{x}_{ au}|\mathbf{x}_0,D_{ heta}(\mathbf{y})) = \mathcal{N}_{\mathbb{C}}(\mathbf{x}_{ au};\; oldsymbol{\mu}_{\mathsf{reg}},\; \sigma(au)^2 \mathbf{I})$$

Where the mean is:

$$oldsymbol{\mu}_{\mathsf{reg}} = \mathsf{e}^{-\gamma au} \, \mathbf{x}_0 + \left(1 - \mathsf{e}^{-\gamma au}
ight) D_{ heta}(\mathbf{y})$$

- This defines a Gaussian perturbation around a learned target $D_{\theta}(\mathbf{y})$.
- As $\tau \to \infty$, the distribution converges toward $D_{\theta}(\mathbf{y})$.

Gavish Bansal Diffusion Models August 2, 2025 49 / 79

Score Function and Training Objective

Adapted Score Function:

$$abla_{\mathbf{x}_{ au}} \log p_{ au}(\mathbf{x}_{ au} \mid D_{ heta}(\mathbf{y})) = -\frac{\mathbf{x}_{ au} - \boldsymbol{\mu}_{\mathrm{reg}}}{\sigma(au)^2}$$

Combined Training Objective (StoRM):

$$\mathcal{J}^{(\mathsf{StoRM})} = \alpha \mathcal{J}^{(\mathsf{Sup})} + (1 - \alpha) \mathcal{J}^{(\mathsf{DSM})}$$

Where:

$$egin{aligned} \mathcal{J}^{(\mathsf{Sup})} &= \mathbb{E}\left[\|\mathbf{x} - D_{ heta}(\mathbf{y})\|_2^2
ight] \ \mathcal{J}^{(\mathsf{DSM})} &= \mathbb{E}\left[\left\|\mathbf{s}_{\phi}(\mathbf{x}_{ au}, [\mathbf{y}, D_{ heta}(\mathbf{y})], au) + rac{\mathbf{z}}{\sigma(au)}
ight\|_2^2
ight] \end{aligned}$$

- $\mathcal{J}^{(Sup)}$ encourages direct supervised reconstruction.
- $oldsymbol{ ilde{\mathcal{J}}^{(DSM)}}$ trains the score network to match the Langevin-inspired score.
- $oldsymbol{lpha} lpha \in [0,1]$ balances between supervised and denoising-score-matching

Gavish Bansal Diffusion Models August 2, 2025 50 / 79

Inference Procedure

Generate initial estimate:

$$\hat{\mathbf{x}}^{(0)} = D_{\theta}(\mathbf{y})$$

Sample starting point:

$$\mathbf{x}_{\mathcal{T}} \sim \mathcal{N}_{\mathbb{C}}(\hat{\mathbf{x}}^{(0)}, \sigma^2(\mathcal{T})\mathbf{I})$$

- **③** Take reverse steps from $x_T \to x_0$ as done in simple SDE algorithm.
- ullet Final output: \mathbf{x}_0 after T steps

Pseudocode Training

Algorithm 1 StoRM Training

Input: Training set of pairs (\mathbf{x}, \mathbf{y}) **Output**: Trained parameters $\{\phi, \theta\}$

- 1: Sample diffusion time $t \sim \mathcal{U}(t_{\epsilon}, T)$
- 2: Sample noise signal $\mathbf{z} \sim \mathcal{N}(0, \mathbf{I})$
- 3: Infer initial prediction $D_{\theta}(\mathbf{y})$
- 4: Generate perturbed state $\mathbf{x}_{\tau} \leftarrow \boldsymbol{\mu}(\mathbf{x}, D_{\theta}(\mathbf{y}), \tau) + \sigma(\tau)\mathbf{z}$
- 5: Estimate score $\mathbf{s}_{\phi}(\mathbf{x}_{\tau}, [\mathbf{y}, D_{\theta}(\mathbf{y})], \tau)$
- 6: Compute loss $\mathcal{J}^{(\operatorname{StoRM})}(\phi, \theta)$ (eq. (17))
- 7: Backpropagate loss $\mathcal{J}^{(\mathrm{StoRM})}(\phi, \theta)$ to update $\{\phi, \theta\}$

Figure: Pseudocode(STORM TRAINING)

Pseudocode Inference

Algorithm 2 StoRM Inference (based on PC sampling by [44])

Input: Corrupted speech y, step size $\Delta \tau = \frac{T}{N}$ **Output**: Clean speech estimate $\hat{\mathbf{x}}$

- 1: Infer initial prediction $D_{\theta}(\mathbf{y})$
- 2: Sample noise signal $\mathbf{z} \sim \mathcal{N}(0, \mathbf{I})$
- 3: Generate initial reverse state $\mathbf{x}_T = D_{\theta}(\mathbf{y}) + \sigma(T)\mathbf{z}$
- 4: **for** $n \in \{N, \dots, 1\}$ **do**
- 5: Get diffusion time $\tau = n\Delta \tau = \frac{n}{N}T$
- 6: **if** using corrector **then**
- 7: Estimate score $\mathbf{s}_{\phi}(\mathbf{x}_{\tau}, [\mathbf{y}, D_{\theta}(\mathbf{y})], \tau)$
- 8: Sample correction noise signal $\mathbf{w}_c \sim \mathcal{N}(0, \mathbf{I})$
- 9: Correct estimate (Annealed Langevin Dynamics):

$$\mathbf{x}_{\tau} \leftarrow \mathbf{x}_{\tau} + 2r^{2}\sigma(\tau)^{2}\mathbf{s}_{\phi}(\mathbf{x}_{\tau}, [\mathbf{y}, D_{\theta}(\mathbf{y})], \tau) + 2r\sigma(\tau)\mathbf{w}_{c}$$

Limitations of STORM for Clipped Speech

- Our objective is to handle infinitely clipped speech, which poses a unique challenge for traditional speech restoration models.
- The STORM model struggles in this scenario, likely because clipping
 is a non-linear distortion—unlike additive noise, it cannot be
 effectively modeled by simple linear perturbations.
- We hypothesize that a Bernoulli-based diffusion model could offer a better alternative, as it avoids the assumption of linear noise addition.
- In the following slides, we will first understand the Bernoulli diffusion model, and then explore potential adaptations for clipped speech restoration.

Gavish Bansal Diffusion Models August 2, 2025 54 / 79

Bernoulli Autoencoder: Overview

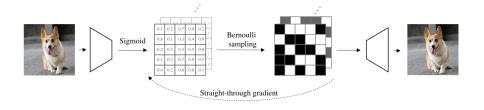

Figure: Enter Caption

- Goal: Learn a compact and expressive binary representation of the input image.
- Architecture:
 - Encoder maps input image x to a feature map $\Psi(x)$.
 - Sigmoid activation converts features to probabilities: $y = \sigma(\Psi(x))$.
 - Binary latent vector z is sampled from a Bernoulli distribution: $z \sim \text{Bernoulli}(y)$.
- Decoder reconstructs the original image from z.

Binary Representation via Bernoulli Sampling

- The encoder outputs real-valued probabilities $y \in [0, 1]$.
- Binary latent code is sampled:

$$z_i \sim \text{Bernoulli}(y_i)$$
, for each element i .

- This introduces a discrete latent space that improves compactness and generalization.
- Sampling from Bernoulli is non-differentiable, which complicates backpropagation.

Gavish Bansal Diffusion Models August 2, 2025 56 / 79

Training with Straight-Through Estimator

- To enable gradient flow through binary samples, the Straight-Through Estimator (STE) is used.
- Forward pass uses sampled binary z.
- Backward pass copies gradients from continuous y:

$$\tilde{z} = \mathsf{StopGrad}(z - y) + y$$

• Allows end-to-end training despite non-differentiable sampling.

57 / 79

Reconstruction and Loss Objective

- Decoder reconstructs $\hat{x} = \Phi(\tilde{z})$ from the binary latent code.
- Training uses a combination of:
 - Mean Squared Error (MSE)
 - Perceptual Loss
 - Adversarial Loss (optional)
- Objective:

$$\mathcal{L} = \lambda_1 \cdot \mathsf{MSE}(x, \hat{x}) + \lambda_2 \cdot \mathsf{Perceptual} + \lambda_3 \cdot \mathsf{GAN} \mathsf{\ loss}$$

 Binary representations are both compact and robust for generative modeling.

58 / 79

Forward Diffusion Process

- **Progressive Noise Addition**: A sequence of conditional distributions $q(z^t|z^{t-1})$ progressively adds noise to the binary latent code over T steps.
- Starting Point: The process begins with the original binary latent code $z^0 \sim q(z^0)$, which is the output of the auto-encoder's Bernoulli sampling.
- Bernoulli Noise Definition:

$$q(z^{t}|z^{t-1}) = \mathcal{B}(z^{t}; z^{t-1}(1-\beta^{t}) + 0.5\beta^{t})$$

- β^t is a pre-defined noise schedule (e.g., increasing from a small value to 1).
- This formulation ensures that as β^t increases, the probability of flipping bits also increases.
- **Convergence**: As $t \to T$, the latent code z^T converges to a random Bernoulli distribution:

$$z^T \sim \mathcal{B}(z^T; 0.5)$$

Gavish Bansal Diffusion Models August 2, 2025 59 / 79

- **Objective**: To generate new binary latent codes, we need to reverse the diffusion process. This involves training a neural network f_{θ} to approximate the true reverse conditional probability $p_{\theta}(z^{t-1}|z^t)$.
- Reverse Conditional Distribution:

$$p_{\theta}(z^{t-1}|z^t) = \mathcal{B}(z^{t-1}; f_{\theta}(z^t, t))$$

- $f_{\theta}(z^t, t)$ is the learned function that predicts the probability of $z^{t-1} = 1$ given z^t and the current timestep t.
- **Sampling**: By starting from a noisy sample z^T (from $\mathcal{B}(z^T; 0.5)$) and iteratively applying f_θ for T steps, we can obtain a clean binary latent code $z^0 \sim q_\theta(z^0)$.

Gavish Bansal Diffusion Models August 2, 2025 60 / 79

Loss function

It is easy to derive :

$$q(z^t \mid z^0, z^T) = \mathcal{B}(z^t; k^t z^0 + b^t),$$
 with

$$k^t = \prod_{i=1}^t (1 - \beta^i),$$

$$b^{t} = (1 - \beta^{t})b^{t-1} + 0.5\beta^{t}$$
, and $b^{1} = 0.5\beta^{1}$,

• It can be seen that k^t and b^t are very closely related by the following equation:

$$b^t = .5(1 - k^t)$$

• So, instead of β^t we can directly fix k^t and use it to find corresponding b^t .

◆ロト ◆個ト ◆差ト ◆差ト 差 めるぐ

Loss function

Now, using the same derivation done for normal diffusion models:

$$\begin{split} \mathcal{L}_{\mathsf{vlb}} &:= \mathcal{L}_0 + \sum_{t=1}^{T-1} \mathcal{L}_t + \mathcal{L}_T \\ &:= -\log p_{\theta}(z^0 \mid z^1) \\ &+ \sum_{t=1}^{T-1} \mathsf{KL}\left(q(z^{t-1} \mid z^t, z^0) \parallel p_{\theta}(z^{t-1} \mid z^t)\right) \\ &+ \mathsf{KL}\left(q(z^T \mid z^0) \parallel p(z^T)\right). \end{split}$$

- Here $q(z^{t-1} \mid z^t, z^0)$ is given by equation on previous slide.
- $p_{\theta}(z_{t-1} \mid z_t)$ is model output.

Gavish Bansal Diffusion Models August 2, 2025 62 / 79

Reparameterization Techniques (1/2)

Predicting the Original Latent Code z^0

- **Challenge**: Direct prediction of z^{t-1} is complicated due to changing noise levels across timesteps.
- **Strategy**: Predict the original clean latent code z^0 directly.
 - The model $f_{\theta}(z^t,t)$ is trained to estimate \hat{z}^0 , the original binary code.
 - This simplifies the learning target, as z^0 is a clean, noise-free binary representation.
 - Learning $P(z^0|z^t)$ is theoretically equivalent to learning $P(z^{t-1}|z^t)$.
 - However, empirical results show predicting z^0 often leads to better performance and training stability.

Gavish Bansal Diffusion Models August 2, 2025 63 / 79

Reparameterization Techniques (2/2)

Predicting Residual Bit Flips

- **Strategy**: Predict the residual (bit flips) between z^t and z^0 .
 - The model $f_{\theta}(z^t, t)$ is trained to estimate $z^t \oplus z^0$, i.e., which bits were flipped.
 - This approach leverages the sparsity of flips—especially early in the diffusion process when noise is low.

Advantages:

- Efficiently captures sparse bitwise changes.
- Leads to more stable training and faster convergence.
- ullet The output of $f_{ heta}$ is interpreted as the probability of a bit being flipped.
- Theoretically, this approach is also equivalent to directly predicting z^{t-1} or z^0 , but has practical benefits.

Gavish Bansal Diffusion Models August 2, 2025 64 / 79

Reparameterization: Predicting z^0

• Directly model $p_{\theta}(\mathbf{z}^0|\mathbf{z}^t)$ via:

$$\hat{\mathbf{z}}^0 = f_{\theta}(\mathbf{z}^t, t)$$

• Reconstruct $p_{\theta}(\mathbf{z}^{t-1}|\mathbf{z}^t)$ using Bayes' rule:

$$p_{\theta}(\mathbf{z}^{t-1}|\mathbf{z}^t) = \sum_{\mathbf{z}^0 \in \{0,1\}} q(\mathbf{z}^{t-1}|\mathbf{z}^t,\mathbf{z}^0) p_{\theta}(\mathbf{z}^0|\mathbf{z}^t)$$

Explicit form:

$$p_{\theta}(\mathbf{z}^{t-1}|\mathbf{z}^t) = \left(\mathbf{z}^{t-1}; \frac{A}{A+B}\right)$$

where
$$A = [(1 - \beta^t)\mathbf{z}^t + 0.5\beta^t] \odot [k^t f_\theta + 0.5b^t],$$

 $B = [(1 - \beta^t)(1 - \mathbf{z}^t) + 0.5\beta^t] \odot [k^t(1 - f_\theta) + 0.5b^t].$

Gavish Bansal Diffusion Models August 2, 2025 65 / 79

Residual Parameterization via XOR

Predict flipping probability (XOR residual):

$$f_{\theta}(\mathbf{z}^t,t) \approx \mathbf{z}^t \oplus \mathbf{z}^0$$

• Training objective (Binary Cross-Entropy):

$$\mathcal{L}_{\mathsf{residual}} = \mathbb{E}_{t, \mathbf{z}} \left[\mathsf{BCE}(\mathit{f}_{\theta}(\mathbf{z}^t, t), \mathbf{z}^t \oplus \mathbf{z}^0) \right]$$

Combined loss:

$$\mathcal{L} = \mathcal{L}_{\mathsf{residual}} + \lambda \mathcal{L}_{\mathsf{vlb}}$$

ullet λ balances diversity and stability (empirically $\lambda=0.1$).

8: Compute flipprob = f_{\theta}(\mathbf{z}^T, T)
9: Sample \mathbf{z}^0 \sim \text{Bernoulli}(\text{flipprob} \cdot (1 - \mathbf{z}^T) + (1 - \text{flipprob}) \cdot \mathbf{z}^T)
10: Return \Phi(\mathbf{z}^0)
```
